

- 4 A magic square puzzle corresponds to a matrix of $n \times n$ cells.

Consider, for example, the following 3×3 matrix:

The magic square must then be filled with integers ranging from 1 to n^2 . From the above example, we thus have:

6	1	8
7	5	3
2	9	4

Also notice that when we sum each row (3), column (3) and diagonal (2 – thus, altogether 8 sets of 3 numbers), the sum is always the same. This corresponds to a valid solution to the magic square.

You are tasked to implement an object-oriented class for a magic square puzzle using the UML class diagram below.

MagicSquare
-n: INTEGER -grid: ARRAY OF ARRAY OF INTEGER
+constructor(INTEGER) +swap(INTEGER, INTEGER, INTEGER, INTEGER) +solved(): BOOLEAN +print()

The following are the descriptions of the various attributes and methods within this class.

Attribute/Method	Description									
<code>MagicSquare.n</code> <code>MagicSquare.grid</code> <code>MagicSquare.constructor</code> (<code>INTEGER</code>)	<p>The <code>MagicSquare</code> class contains two attributes: <code>n</code>, the length of each side of the matrix; and <code>grid</code>, the actual contents of the matrix. The maximum value for <code>n</code> should be 10. If a value larger than 10 is specified, an exception should result.</p> <p>On construction, the contents should be the integers 1 to n^2, in order (left column to right column, then top row to bottom row). For example:</p> <table><tr><td>1</td><td>2</td><td>3</td></tr><tr><td>4</td><td>5</td><td>6</td></tr><tr><td>7</td><td>8</td><td>9</td></tr></table>	1	2	3	4	5	6	7	8	9
1	2	3								
4	5	6								
7	8	9								
<code>MagicSquare.swap()</code>	<p>This method takes in 4 integer parameters:</p> <table><tr><td>AR</td><td>ROW index of CELL A</td></tr><tr><td>AC</td><td>COLUMN index of CELL A</td></tr><tr><td>BR</td><td>ROW index of CELL B</td></tr><tr><td>BC</td><td>COLUMN index of CELL B</td></tr></table> <p>Each of the above must be in the range 0 and $(n - 1)$. The method will then swap the values in <code>grid[AR, AC]</code> and <code>grid[BR, BC]</code>.</p> <p>Specification of a value outside the required range must result in an exception.</p>	AR	ROW index of CELL A	AC	COLUMN index of CELL A	BR	ROW index of CELL B	BC	COLUMN index of CELL B	
AR	ROW index of CELL A									
AC	COLUMN index of CELL A									
BR	ROW index of CELL B									
BC	COLUMN index of CELL B									
<code>MagicSquare.solved()</code>	<p>Checks if the <code>grid</code> is ordered in such a way that it satisfies the conditions for a solved magic square. This method will return <code>True</code> if this is the case, else returns <code>False</code>.</p>									
<code>MagicSquare.print()</code>	<p>Prints the contents of <code>grid</code>. This output should include pretty printing of cell boundaries.</p>									

Task 4.1

Implement the `MagicSquare` class. Only implement the constructor and print methods. Do **not** implement the `swap` and `solved` methods (yet).

Evidence 20

- The program code for the `MagicSquare` class (excluding the `swap` and `solved` methods). [3]

Task 4.2

Implement the `swap` method for the `MagicSquare` class.

Evidence 21

- The program code for the `swap` method. [2]

Task 4.3

Implement the `solved` method in the `MagicSquare` class.

Evidence 22

- The program code for the `solved` method in the `MagicSquare` class. [5]

Now that you have a working implementation of a magic square. You are to write a program to solve a magic square.

You should only utilise the `swap` method within the `MagicSquare` class to manipulate the `grid` attribute.

Your program should work for any value of `n`.

Task 4.4

The program code to initialise a random sized magic square between 5 and 10, and to solve that magic square.

Evidence 23

- The program code for **Task 4.4**. [10]
